

\$ALL: A Shared Community Currency

Kevin Ricoy
kevin@allmight.us
<https://twic.tv>

Abstract. Crypto made it possible to own and trade a piece of anything – a community, a social trend, a joke, a movement, an idea they were early to believing in – instantly, with no bank, no broker, and no one's permission. And yet, almost all of that capability has been spent building casinos: zero-sum games of musical chairs where the sole utility is to sell a worthless token before the illusion shatters for everyone else, and the farce of “believing in something” collapses. In other words...the most loyal believers are punished the hardest, and become the greatest fools. The prevailing assumption is that this is what the technology is for, that the speculation, the community, and the fraud are one inseparable product. They are not. This paper describes \$ALL, a shared currency designed for *many* communities and businesses that can generate real consumptive demand, beginning with one: This Week In Crypto, a crypto media property and community which enters first, in public, as the anchor tenant. Designing beyond a token for the singular property expands the ultimate ceiling beyond the attention of any one meme, creator, or even community, to rival that of a real world currency, with a collective ecosystem of goods and services, and, most importantly, consumers. \$ALL is fairly launched on a fully reserved public curve. No one receives a free allocation, a discount, or a reward for anything other than bringing paying customers into the economy. There is no fundraiser, there is no Foundation, and there is no investment contract.

1. Introduction

People should be able to own a piece of the things they love. The technology that makes this possible is not going away, and it shouldn't.

So far this technology has produced a ladder of tokens, each with a higher ceiling than the last (Figure 1). The creator coin is bound to one person's reach and dies with that person's relevance: burnout, scandal, or the algorithm moving on. The celebrity coin is the same instrument with a bigger audience, where fame arrives as a spike and decays. The community coin is the first meaningful break from this structure: it detaches from any individual, which is why Dogecoin has outlived its founders' involvement and every cycle that was supposed to kill it. But its demand is still a sense of belonging. People hold it to be in on something, so its ceiling is a headcount: the number of people who identify, times what they will park in their casino chips.

The fourth tier changes dimension rather than size. An economy currency's ceiling is not measured in people but in flow: the money a currency must hold is proportional to the commerce that runs through it, so the ceiling stops being “how many fans exist” and becomes “how much business denominates in this,” a GDP-shaped number with no headcount cap. Fans saturate; commerce compounds. This paper is about the fourth tier. A tier-three coin cannot mature into a tier-four currency, because its demand type is wrong from birth; and thus, \$ALL is ambitiously designed for consumption from day one rather than not at all.

Figure 1: The ceiling hierarchy. The first three tiers are bounded by a stock of people; the fourth is bounded by a flow of commerce. The constraint does not just grow at the last step, it changes kind.

The ceiling ordering is not a probability ordering. Each step up trades a higher ceiling for a harder coordination problem, and the graveyard runs exactly the other way. Dead creator coins are countless. Dead economy currencies include Kin, the ecosystem-currency project spun out of Kik. Kin had a nine-figure war chest, a built-in audience of millions, a rewards engine purpose-built to pay developers for joining, and it still lost a landmark SEC case and never solved the problem of the second contributor. This paper exists because we think we now know which parts of that design were the problem and which were merely the victim of timing.

The short version: Kin sold tokens to fund its issuer, allocated 30 percent to insiders, and paid for adoption with inflationary rewards that were promptly gamed. \$ALL does none of these things. No one sells you \$ALL. No one is allocated \$ALL. No one is rewarded in \$ALL for activity or “bagworking”. The only way anyone acquires it is by purchasing it from a public reserve at a published price, so the force designed to move that price is customers buying the currency to consume something real.

This paper will not ask you to believe anything. Section 4 gives you the exact mathematics of what early and late participation are worth, including the case against joining. Section 10 lists every claim you can check yourself. Section 11 states, in advance, what failure looks like.

2. The Reserve

\$ALL launches via Flipcash, a wallet simple enough for people with no crypto experience, which allows anyone to create a currency they can actually use like money. Every Flipcash currency holds a real US Dollar reserve, so there is always a redemption value greater than zero. The signature move of the casino, where insiders pull liquidity and holders are left with a number that rounds to nothing, is not available here. The reserve is a structural answer to the rug.

The reserve is not a promise but an equation. Every Flipcash currency redeems against its reserve according to:

$$\text{Redemption Value} = \$11,400.2301 \times (e^{(0.00000087717527 \times \text{Units Issued})} - e^{(0.00000087717527 \times (\text{Units Issued} - \text{Units Redeemed}))})$$

We did not take this on faith. We tested it independently, including the scenario that matters most: if every holder redeems at once, the reserve pays out exactly what was deposited, to the penny, draining to precisely zero and never below. The contract cannot be bank-run into insolvency, because it is never fractional.

One qualification, stated here rather than buried: a floor under the currency is not a floor under your position. Buy high, and if enough people redeem, you can still receive back less than you paid. And every property in this section holds only so long as Flipcash's reserve contract is non-custodial and cannot be altered after deployment, which is a thing to verify rather than accept, and which is why the contract address appears in Section 10.

3. Issuance

A currency that begins with a hidden insider supply is an extraction depot with extra steps. \$ALL has none, and given the author's history, the contrast is worth spelling out.

Kin launched with roughly 30 percent of supply allocated to Kik and a foundation controlling most of the rest, plus a rewards engine that circulated currency for measured activity, which participants promptly learned to fabricate. Every one of those mechanisms created supply that someone received for free and could sell into demand that someone else paid for.

\$ALL's total supply is fixed at 21,000,000 units, with no mechanism to create more. There is no foundation, no pre-mine, no presale, no private round, no rewards engine, and no allocation issued to anyone at any price other than the public one. Every unit that will ever exist is purchased with US Dollars

from the reserve at the prevailing price on the curve. The team buys on the same public curve as everyone else, and its holdings are not a matter of trust: they are held at [ADDRESS], locked until [DATE], and disclosed as a percentage of supply in Section 9. If that address moves before the lock expires, this paper has been violated and you should say so loudly.

There is exactly one way to benefit from \$ALL beyond holding it, and it is the same for everyone including us: bring customers into the economy who purchase the currency to spend it.

4. The Mathematics of Joining Late

This is the section other papers do not write. The curve rewards earlier participants more than later ones. Rather than mumble that fact in a risk disclosure, we will hand you the equation and the argument for staying out.

For any participant who purchases D dollars of \$ALL when the reserve stands at R, their maximum redemption value once the total reserve reaches T is exactly:

$$V = (T + 11,400.23) \times D / (R + D + 11,400.23)$$

Read it plainly: your position is a fixed share of the total reserve, and that share is set forever by how large the reserve was when you entered. A community bringing \$50,000 into a \$1M economy captures about 4.7 percent of every dollar that arrives after it. The same community entering at \$10M captures 0.5 percent. At \$100M, 0.05 percent. The tide can rise for everyone, and with consumptive demand we expect it to, but the boats are unequal and the ratio is fixed at the dock.

This produces what we call the franchise premium. A community that could attract outside demand to its own solo coin gives that up by joining \$ALL, and the shared network must out-generate that solo alternative by roughly the ratio of the network's size to the community's own, just to break even. A community one-seventeenth the size of the network needs the network to pull seventeen dollars for every dollar it could have pulled alone.

The consequence is an adverse-selection pressure we would rather name than have discovered: joining is mathematically dominant for communities too small to bootstrap demand alone, and mathematically inferior for communities large enough to go solo, with the boundary tightening as \$ALL grows. If you run a community with real independent demand and you are reading this to decide, the honest answer may be: launch your own. Flipcash makes it free, and this paper's math tells you when. What \$ALL offers in exchange for entering late is everything that is not on the curve: a shared pool of advertisers and audiences most communities could never attract alone, interoperability, distribution through the network's media properties, and one mechanism that runs the other direction, described next.

5. Consumptive Demand

Here is the difference between an economy and a memecoin: with a memecoin, the only reason to buy is that someone later will buy; in an economy, people acquire the currency because they want the things it purchases.

Every demand mechanism in \$ALL is consumptive. Advertisers purchase \$ALL to buy clearly labeled ad inventory on participating shows and platforms. Fans purchase it to put their memes and questions on the air, to enter contests, to tip each other, to buy access and merchandise from participants. In each case the buyer receives full value at the moment of purchase. A late participant who bought \$ALL, spent it on an advertising slot, and received the advertising is not a victim of anything, regardless of whatever the chart may do afterward. The appreciation earlier holders enjoy is funded by customers who got what they paid for, just like a real currency (which is a different thing, economically and morally, from being funded by speculators who hoped to exit onto someone else).

“Nobody gets anything for free” is the entire incentive design. Participants who want their position in \$ALL to grow have exactly one lever: bring more paying customers into the economy to pay you in \$ALL. There is no engine to game because there is no engine, only revenue.

One mechanism deserves its own paragraph because it runs against the gradient in Section 4. A disclosed portion of \$ALL received as advertising payment is burned, permanently retiring that supply. A burn accrues to every outstanding holder pro-rata, regardless of when they entered. It is the one flow in the system that treats the latest participant identically to the earliest, and it is why the ad economy is not merely \$ALL's largest demand source but its fairness valve. The burn split is fixed in Section 9 and verifiable in Section 10.

What consumptive demand does not do is repeal arithmetic. The reserve is zero-sum on dollars: aggregate exits can never exceed aggregate deposits, and the trajectory of the currency is exactly the trajectory of net inflows. Real revenues make persistent inflows plausible. They do not make them guaranteed, and anyone who tells you a currency can only go up is selling you the previous decade.

6. The Anchor Tenant

An economy of many participants has to start with one, and the first participant takes the worst deal in this paper: full exposure, zero information asymmetry, and a public document to be held against them.

This Week In Crypto enters first. Not as issuer, because there is no issuer; as the first business to denominate its services in \$ALL and eat its own cooking in public. From launch, TWIC's economy runs on \$ALL:

Money. \$ALL is a currency you can actually use like cash. Send any denomination to anyone on Flipcash as easily as handing someone a bill. Pay people back, settle up, tip.

Ad Inventory. Sponsors buy TWIC's advertising slots with \$ALL. This is likely the largest recurring source of consumptive demand at launch: businesses acquiring the currency not as a bet but to pay for something real. Of \$ALL received in ad payment, [50]% is redeemed to cover income taxes and fund operations and [50]% is burned under the mechanism in Section 5.

Community Spotlight. Spend \$ALL to put a meme, a take, or a question on camera in the community segment. The show has airtime; the audience wants it. The prohibition in Section 7 applies: this buys fun, never coverage.

Contests. Trivia and meme competitions, entered with a small amount of \$ALL, winners taking a pot and a feature. Skill and timing, not wagers on price; a news program inducing its audience to bet on the markets it reports on is exactly the behavior this document exists to oppose.

Status. Holder tiers unlocking gated rooms, leaderboards, and badges, arriving after launch.

Every future participant plugs in the same way: denominate your services in \$ALL, keep your brand, run your own spotlight and your own inventory, capture your own revenue. The network's job is to make your customers' dollars and everyone else's customers' dollars the same dollars.

7. Editorial Independence

This section was hard to write for a single-community token. It is harder now.

TWIC is a news show whose only real asset is that its audience believes it. With \$ALL, the conflict is no longer limited to one coin: the show covers an industry it is simultaneously inviting into a currency its team holds. Every story about any company is now a story about a potential participant. The firewall therefore has to be absolute rather than merely careful:

The show does not cover \$ALL. Not favorably, not neutrally, not as news. The token's existence is disclosed on every episode and in every published piece, and that disclosure is the only editorial acknowledgement it receives. Coverage of any project, company, or token is never for sale and never influenced by whether the subject participates in, competes with, or refuses \$ALL. Recruitment of participants is business development, conducted by named people who do not make editorial decisions, and no editorial staffer is compensated in ways tied to \$ALL's value. Ads are clearly labeled, sold at arm's length, and payable in \$ALL, and because a token advertisement on a token-news show re-imports the conflict through the side door, projects and tokens the show could conceivably cover are not eligible advertisers, in any currency, at any price.

A media company demonstrating that it can build something it profits from without corrupting the thing its audience trusts is part of the point. The first time the bag bends what the show says, the show is worthless, and so, deservedly, is the currency.

8. The Absence of a Promise

\$ALL makes no promise of a return. We do not claim it will appreciate, we do not imply it, and we do not wink at it. What this paper does instead is describe the mechanics exactly, including the ones that favor us as early participants, and let you do arithmetic instead of hoping.

This is deliberate. We are removing the whisper and publishing an equation. If anyone, including us, ever frames “get in early” as a profit tip rather than a disclosure, treat it as the warning sign it is.

9. Disclosures

This section contains no jokes. If only one section is read, it should be this one.

- **Supply.** 21,000,000 \$ALL, fixed. No mechanism exists to mint additional units.
- **Acquisition.** Units are purchased from the Flipcash reserve at the current curve price. No presale, private round, allocation, or reward program exists or will exist.
- **Team holdings.** [X]% of supply, purchased on the public curve, held at [ADDRESS], locked until [DATE], verifiable on-chain at any time. The team does not sell into community enthusiasm.
- **Early participation.** The curve rewards earlier participants more than later ones, per the equation in Section 4. This is disclosed mathematics, not a reason to hurry.
- **Zero-sum reserve.** Aggregate redemptions can never exceed aggregate deposits. Appreciation for any holder is funded by subsequent deposits; in this design those deposits are intended to be consumptive purchases by customers receiving full value, and Section 5 explains why that distinction matters and what it does not change.
- **Advertising.** Participating shows sell clearly labeled ad inventory payable in \$ALL. Ads are never presented as coverage. Of \$ALL received by TWIC in ad payment, [X]% is redeemed for operations and [Y]% is burned; this split is fixed here and any change will be announced before it takes effect.
- **Not an investment.** Nothing herein is financial, legal, or tax advice. \$ALL is a currency for use within a network of participating communities. No representation is made that it will rise in value; assume that it can fall.
- **Regulatory status.** United States digital-asset market-structure legislation is pending and unsettled as of this writing. The design choices in Sections 3 and 5 are made in good faith under existing law, and this paper will be amended if the law requires it. The author's history with Kin is disclosed in Section 1 and informs, but does not immunize, this design.

- **Risk.** Loss of some or all funds is possible, and even likely. Crypto is volatile. Flipcash is a third-party platform whose contracts, custody model, and longevity are independent of ALLMIGHT and should be understood before participating. Do not commit funds you cannot afford to lose.

10. Verification

A paper that says “don't trust, verify” and then gives you nothing to verify is just a longer tweet. Here is every material claim in this document, paired with the means of checking it.

Claim	How to verify
Fixed supply of 21,000,000	On-chain: [TOKEN / MINT ADDRESS]
Reserve contract and redemption curve	Contract: [RESERVE CONTRACT ADDRESS]
Contract is non-custodial and non-upgradeable	[AUDIT LINK / UPGRADE-AUTHORITY STATUS]
Team holdings, lock, and any movement	Watch address: [ADDRESS], lock expiry [DATE]
No presale, allocation, or reward issuance	Full issuance history on-chain from block one
Redemption equation and Section 4 mathematics	Reproduce them yourself, or see our worked verification at [LINK]
Ad-revenue burn split honored	Burns visible on-chain at [BURN ADDRESS / MECHANISM]
This document is unaltered	SHA-256 hash of this PDF: [HASH], published at [LOCATION / TX] on [DATE]

If any entry in this table cannot be filled in truthfully by launch day, the launch waits. That is not a marketing sentence; it is the publication criterion for this paper.

11. Failure Conditions

Every project in this space explains how it might succeed. None define failure, which is precisely what makes their success claims unfalsifiable. So, in advance:

This experiment has failed if the currency is not used: if, after a reasonable period, \$ALL is held only as a bet and not spent on advertising, spotlights, contests, tips, and the things a currency is for. It has failed if, within a horizon we will state publicly at launch, no participant beyond TWIC has joined and built real consumptive demand, because a shared currency with one participant is a community coin wearing a bigger name, and we will say so and treat it as one. It has failed if sustaining it ever requires promotional pressure from the show, because a currency that must be advertised into existence is a speculation with a mascot. And it has failed catastrophically if it ever compromises a single editorial decision.

If it fails, we will say so on the show, plainly, stop building on it, and let it wind down through the same reserve that guaranteed the floor on the way up. What we will not do is quietly pivot the story, relaunch under a new ticker, or pretend the experiment was something other than what this paper says it is. The reserve means even our failure can't rug you. That is the point of the architecture.

12. Conclusion

A reasonable objection: who is this team to try the ecosystem currency again, given how the last one went? The honest answer is that failure is the only training data anyone has for this problem, and we have more of it than most. Kin taught us what breaks: insider supply, simulated demand, and a story about

future contributors doing the work. \$ALL is built from the negations: no insider supply, only purchased demand, and a founding document that hands prospective contributors the mathematics of refusing us.

We do not claim \$ALL fixes crypto, and we do not claim it will become what its name implies. We claim it is a fair test of a specific proposition: that a currency can grow across communities when every dollar entering it buys something real, and that the way to earn trust in this industry is to publish the argument against yourself and then be worth joining anyway.

Either way: the equation is in Section 4, the receipts are in Section 10, and the first economy is open. The price was never the point.
